Cloud Classification of DMSP visible and IR Imagery Using Physical and Textural Features

Andreas K. Goroch and R. N. Welch

Naval Oceanographic and Atmospheric Research Laboratory

and

Institute of Atmospheric Science North Dakota School of Mines and Technology

1 Summary

Cloud features have an important impact on global Navy activities, ranging from the effects of clouds on surface ship and aircraft operations to the limitation and enhancement of surfeillance activities. We have been developing an automated system for the recgnition of operationally important cloud types using data obtained from the Defense Meteorological Satellite Program (DMSP) satellite system. The satellite is deployed in a sun-synchronous morning orbit, and carries a variety of sensors, including the Optical Line Scanner (OLS). This paper describes ongoing work in the use of physical and textural measures for the automatic recognition of cloud classes. We have found the physical measures to be relatively computer intensive, and dependent on visible and IR satellite data. The addition of textural measures shows promise for enhancing the classification capability by using only a single channel and by reducing computer processing time.

2 DMSP Data analysis

Satellite image data from the DMSP Optical Lines Scanner are received at FNOC within two hours of observation. The OLS data are measured in two spectral bands, visible and thermal infrared, with constant ground resolution across the satellite swath. The data are immediately transformed to the Quadrilateralized Spherical Cube coordinate system (Chan and O'Neill, 1978). This coordinate system is particularly suited to objective image analysis, since the coordinate system is area preserving, providing a constant ground resolution anywhere on the globe. The satellite data are stored in 64 by 64 pixel interpolation blocks (IB). overlaps from different orbits are permitted among the same orbit.

The coordinate system is ideal for multispectral analysis since the data are located on a equal area projection, with the same resolution for visible and IR channels

3 Image feature derivation

The digital imagery are analyzed within each interpolation block. The earlier physical image analysis (Garand, 1988, Goroch, 1988) have been found to be computer intensive, and inefficient on the Cyber 175 computer system in use at FNOC. The analysis was expanded to include textural measures (Welch, 1986) in an effort to provide a graded system of cloud classification. The current objective is to analyze the image with progressively more complex classification measures, until a required confidence level is attained.

4 Physical features

The physical features of the visible and infrared image have been described by Garandand Weinman (1986) and Ebert (1988) and are summarized in table 1. The features are combined into an image

Special	1

vector which is normalized and used in later feature discrimination. The physical meaning of the feature vector is determined by its use in the function discriminating among cloud types. In the current use of a Gaussian multivariate type of discriminant function, the elements of the feature vector of a category provide the following information

Element negative - feature reduces class membership

Element zero - class membership distributed around mean

Element positive - feature increases class membership

The Garand cloud classes were obtained from a training set of GOES data during the winter of 1984 in the northwest Atlantic. The classifications are shown in Table 2, together with objective characteristics of each cloud type. Figure 1 shows the characteristic feature vectors associated with low layered cloud types. Note, for example, the improtance of the MC, multilayer, element in differentiating the altocumulus cloud type from the two multilayered cloud types, Cumulus with Altocumulus and Stratocumulus with Altocumulus.

Table 1
Physical characteristic vectors

Description	Limits
Crosscorrelation (ST.)	(0,1)
Spectral Intensity between 20-40 km (SE)	(0,1)
mean cloud albedo (AL)	(0,1)
Cloud top height(HT)	Ø - 14 km
Background connectivity (BC)	(0,1)
IR low cloud fraction (LO)	(0,1)
IR middle cloud fraction (MI)	(0,1)
Multilayer index (ML)	(0,1)
Total cloud fraction (CF)	(0,1)
Number of clouds (NC)	
Fraction of cirrus clouds (LR)	(0,1)
Cloud Connectivity (CC)	(0,1)
High Cloud fraction (HI)	(0, 1)

5 Textural features

To supplement the physical features, we have added the textural features used by Welch(1986) and others for class discrimination. The textural features are shown in Table 3. The textural features provide a rapid textural analysis which it was considered would add to useful measures, which would not use every much computer time.

Table 2 - Physical class characteristics

Гуре	Cloud	Cloud Fraction		Texture	Character	Visible Albedo			TR Height		
	Hin	Тур	Hax			Min	Тур	Нах	Hin	Typ	Hax

Grey Shade Co-Occurrence Calculation Functions
$$D_{f,N(l,p,d)} = f(V(l,p),V(l,p+d))$$

$$D_{f,V(l,p,d)} = f(V(l,p),V(l+d,p))$$
Where $f = sum$, difference, Absolute value of difference
$$P_d(D) = \frac{N(D_N - D.D_V - D)}{N(D_V.D_N)}$$
Grey Shade Co_occurrence Texture Heasures
$$Maan = \frac{1}{N_{shades}} \sum_{i}^{N_{shades}} t^2 P(i)$$

$$Second Moment = \frac{1}{N_{shades}} \sum_{i}^{N_{shades}} (1 - Maan)^2 P(i)$$

$$Distribution Square = \frac{1}{N_{shades}} \sum_{i}^{N_{shades}} P(i) \log(P(i))$$

$$Contrast = \frac{1}{N_{shades}} \sum_{i}^{N_{shades}} t^2 P(i)$$

$$Homogeneity = \frac{1}{N_{shades}} \sum_{i}^{N_{shades}} t^2 P(i)$$

$$Shading = \frac{1}{N_{shades}} \sum_{i}^{N_{shades}} (i - Maan)^3$$

$$Prominence = \frac{1}{N_{shades}} \sum_{i}^{N_{shades}} (i - Maan)^4$$

The textural features were calculated by determining the frequency of occurrences of differences, sums and absolute differences in pixel values between pixels separated by d pixels. The current analysis was conducted for separations of $d=\emptyset$, adjacent cells, and d=1, separated by one intervening pixel. only vertical and horizontal separations were used.

The textural features were calculated over each IB with a difference of 1 and 2. In addition the textural features were calculated over sub blocks within the IB. The means and standard deviations of the sub block statistics were saved for the analysis.

6 Feature Discrimination

The feature discrimination function is required to separate class types reliably. Our current classification function is the Mahalanobis distance, which is the multidimensional analogue of the Gaussian distribution function. The category means and crowwcorrelations are those determined by Garand (1986) and Garand and Weinman(1986).

An example of the feature classification is the classification of the West Coast on Oct 5, 1989. The general region chosen for classiffication was between 30N and 40 N in latitude and 122W and 128W in longitude. Near simultaneous GOES imagery of the region are shown for the visible (Figure 2) and the infrared (Fig.3). The region chosen was the area behind a frontal passage, characterized by a variety of stratus and stratocumulus features.

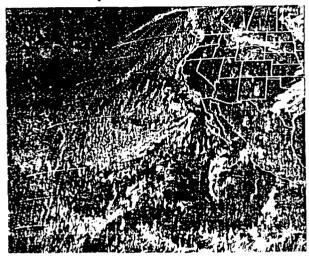

Figure 2 - GOES Visible Image of Analysis

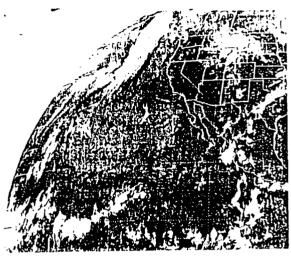

Figure 3 - IR image of analysis

The physical classifier was used to classify 24 regions within the image. Each IB was separated into 4 32 x 32 pixel squares which were used for individual analysis. The initial predictions were found to be highly skewed to clear classifications. The classifier was changed to eliminate clear values. The resulting first, second, and third choices are shown in Table 4.

The visible image was also analyzed for textural features. Each 64×64 pixel region was analyzed for sum, difference and absolute difference vectors—using the formulation of Eq 2. The three grey level distributions for each distance were used to find the scene texture characteristics of each image.

The 64x64 pixel array was further divided into separate 8X8 pixel blocks. Similar gray shade distributions were calculated for each subregion. The mean and standard deviation of the texture characteristics were calculated, and are shown in Table 5.
